

An example of a decision subtree. The root of this subtree is splitting its images on the pixel 351. The right subtree of this node is not drawn because it would be too large.

Notes:

- the sets of indices do not have to be balanced as seen in the root of this subtree.
- if enough of the images referred to by the indices have the same label, the node is a leaf node
- the value -1 is used to indicate a field in the node is not in-use. (You may choose an alternative approach.)
